A solar thermal collector traps the sunlight or absorbs solar radiation to generate solar energy for various applications. Different types of solar collectors are installed at various locations.

Typically, the solar collectors are roof-mounted installations facing the sun. These devices are constantly exposed to changing weather. Hence, they must be sturdy to withstand natural constraints.

There are varied solar collector types sold in the market. Considering them all, the most basic category of such devices involves a black material surrounding some pipes through which water circulates.

Many types of solar collectors are available to harness solar energy. Typically, they are composed of an absorber plate that gathers the sunlight and uses this solar energy for different applications, such as space heating, pool heating, etc.

Flat Plate Collectors are the most simple and common types of solar collectors that anyone can see in their areas. These are basically metal boxes with a dark-coloured absorber plate and have a transparent glazing cover on the top.

Better known as parabolic troughs, the Line Focus Solar Collectors use the same principle for heating water or air that other collectors do: collecting heat on an absorber plate and then transferring it to the water that's to be heated.
