## Connecting 12v batteries in series

This article delves into the nuances of charging LiFePO<sub>4</sub> batteries in parallel and series arrangements, highlighting the best practices, benefits, and considerations one must consider for optimal performance.

When diving into LiFePO<sub>4</sub> battery charging, understanding the different types of battery connections is foundational. These connections determine how individual cells or packs share electrical current, impacting overall voltage, capacity, and charging dynamics. There are two primary connection configurations:

For advanced applications, like powering electric vehicles or extensive renewable energy systems, LiFePO<sub>4</sub> batteries can be arranged in a combination of series and parallel, known as 'series-parallel' configurations. This setup tailors the battery pack to meet specific voltage and capacity demands, ensuring optimal performance and longevity.

Like other types of battery cells, LiFePO<sub>4</sub> (Lithium Iron Phosphate) cells are often connected in parallel and series configurations to meet specific voltage and capacity requirements for various applications. The following is some information about series and parallel connections before we get into the details further.

For example, if you have two 100Ah LiFePO<sub>4</sub> cells connected in parallel, the combined capacity becomes 200Ah, but the LiFePO<sub>4</sub> charging voltage stays the same as one individual cell. This is useful for applications demanding higher energy storage or extended runtime without an increase in voltage.

Combining series and parallel connections allows for customization of the battery pack's energy (Wh) and power (W) density to suit specific needs, such as in electric vehicles or stationary energy storage systems.

By following these guidelines, you can effectively charge lithium iron phosphate batteries in parallel. For best results, use our top-quality lithium iron phosphate batteries and BMS. Explore our full range of products and take the first step towards more efficient and reliable energy storage solutions.

Remember not to mix batteries of different voltages. Using batteries with varied voltages can lead to uneven charging and discharging rates, which in turn can cause strain and imbalances among the cells.

When connecting the batteries in parallel, you should ensure the battery is within 100 millivolts (100mV or 0.1V); if not, there is an increased chance of battery balancing. So, before connecting the batteries, completely charge them individually and check with the voltmeter.

The charges to charge the battery must be of slightly higher voltage. Low voltage chargers will not affect the battery adversely but cannot provide full rated capacity. While BMS may disconnect the battery when having higher voltages than the above-given requirements.

## Connecting 12v batteries in series

For a successful parallel setup, it's crucial that all four batteries possess the same voltage, capacity, state of charge, and ideally hail from the same manufacturing batch. This uniformity ensures an even distribution of charging and discharging duties across the batteries.
