Policies and ethics

Electrical power distribution is the final stage of an electrical power system, which entails the delivery of electricity to the load. The primary role of this section is to carry the electricity from the transmission lines to the loads in the individual customers to the different strata of society. In the power distribution section of an electrical power system, there are two main subsections: primary distribution and secondary distribution.

When we shift our focus onto to how these radial connections are designed in specific conjuncture to the electrification of rural areas, we notice that the distribution voltages are notably higher in rural areas. This is because the higher the voltages, the fewer the poles that need to be erected for the distribution of the electricity. Most of these distribution connections in rural areas are made of galvanized steel. This strong form of steel permits it to be connected over long distances without the need for too many electric distribution poles.

The parameters that encompass the properties of electricity are not strictly limited to voltage and current. When it comes to electricity, there is a third important property of electricity--frequency. There are primarily two frequencies in which electricity is produced, either 50 or 60 Hz. This electricity is then delivered to domestic customers as single-phase electric power. Seen with an oscilloscope, the domestic power supply in North America would look like a sine wave, oscillating between -170 volts and +170 volts, giving an effective voltage of 120 volts RMS.

Venkatesh is an Electrical and Electronics Engineer from SRM Institute of Science and Technology, India. He is deeply fascinated by Robotics and Artificial Intelligence. He is also a chess aficionado, He likes studying chess classics from the 1800 and 1900's. He enjoys writing about science and technology as he finds the intricacies which come with each topic fascinating.
