Energy information management system

Energy information management system

Energy management information systems (EMIS) are a broad and rapidly evolving family of software tools that monitor, analyze, and control building energy use and system performance. All EMIS deployments can be broken down into three functional elements--capabilities, scope, and stack. These form a system of devices, data services, and software applications that aggregate facility data and help optimize energy use at the building, campus, or agency level. A fourth element, operations, represents the people, organizational processes, and actions recommended to successfully use an EMIS.

The EMIS scope includes all integrated building systems and data sources. These commonly include utility bills, weather data, facility-related data, advanced metering infrastructure, building automation systems, utility control systems, distributed energy resources, internet-of-things devices, electric vehicle charging stations, and geographic information systems.

EMIS operations include the actions enabled or processes improved by EMIS capabilities, and the facilities staff, operators, energy managers, and building occupants who use EMIS to optimize the building, campus, or agency. EMIS are human-in-the-loop tools and will not generate savings unless the energy conservation measures identified by EMIS are acted upon and implemented by people.

Effective energy management solutions are more important than ever due to rising expenses, increased energy demand, and growing environmental concerns. Energy Management Information Systems (EMIS) are useful in this situation.

This in-depth manual will delve into the world of EMIS, examining what they are, how they operate, what they offer, what issues they present, and how they contribute to a more sustainable future.

Modern software systems called Energy Management Information Systems (EMIS) are created to track, manage, and optimize how much energy is used in industrial processes, buildings, and other facilities.

Using EMIS, businesses may gather, examine, and act on real-time energy data to make decisions that will cut costs, increase efficiency, and have the least possible negative environmental effects.

These systems offer a comprehensive picture of energy use across various industries, including data centers, transportation networks, manufacturing facilities, office buildings, and industrial facilities.

EMISgathers energy-related data from various sources, such as meters, sensors, and building automation systems. This data includes information on electricity, natural gas, water, temperature, occupancy, etc. Real-time monitoring ensures that organizations have an up-to-date view of energy usage patterns.

Energy information management system

The collected data is processed and analyzed with advanced algorithms and machine-learning techniques. EMISgenerates insightful reports, dashboards, and visualizations that provide stakeholders with actionable insights into energy consumption trends, anomalies, and potential areas for improvement.

Some EMISincorporate energy modeling and simulation capabilities. This allows organizations to simulate different scenarios and strategies to identify the best ways to optimize energy consumption while maintaining comfort and operational requirements.

EMIScan be configured to send alerts and notifications when energy consumption exceeds predefined thresholds or when anomalies are detected. This proactive approach enables prompt responses to deviations from expected energy usage patterns.
