

Florida microgrids netherlands

The power to switch from fossil fuels to renewable energy sources could rest in the hands of local communities. New research suggests decentralized, smart microgrid systems are capable of providing most, if not all, of our future energy needs. The Netherlands is pioneering a new approach to generating and sharing energy which could mean neighborhoods of the near future could produce their own renewable power.

If optimized effectively, the grids could serve as a focal point in the country's drive to adopt renewable energies. The report's author, Florijn de Graaf, predicts almost half of all EU households will generate renewable energy by 2050, with a third of these working as part of a local energy community.

Sweden leads the charge among EU countries with 53.8% of its energy output generated by renewable sources, already surpassing its 2020 target of 49%. The Netherlands is some way behind with a current total of 6%, but there is room for optimism. Optimized properly, microgrids could play a vital part in supporting efforts to transition to renewable energy systems and meet climate targets.

Currently, microgrids power individual appliances - like cars or heat pumps - in isolation, which places heavy demands on the system; much like an electricity power socket overloaded with too many plugs. As more appliances are added, expensive upgrades may be required to sustain the power supply.

A SIDE network uses an intelligent management system to integrate different components and balance local supply and demand, reducing costs. For example, solar panels collect energy when the sun shines and charge electric vehicles; any surplus power is either stored in a battery or sent by the system to power other houses in the community.

The ultimate goal is to use SIDE technology to create future "Smarthoods" where circular flows of water, food and energy would make communities entirely self-sufficient, recycling water, materials and waste wherever viable.

If the success of the Dutch trials can be replicated at scale, this could dramatically alter the energy landscape and go some way towards achieving the ambitious renewable energy targets set by the Netherlands.

Success on a global scale will depend on many country-specific factors, like energy policy and regulations. Places with plenty of wind, water and sunshine - especially if accompanied by high local electricity prices and costly energy tariffs - should, in theory, be good candidates for microgrids.

A new report funded by the Dutch government finds that microgrid technologies could make a local "techno-economy" 90 percent self-sufficient, through the decentralised sharing of energy at the local level between multiple households.

The new approach could even pave the way for "100 percent self-sufficiency in power, heat, and water, and 50 percent self-sufficiency in food production", according to the report's author, energy systems engineer Florijn de Graaf.

If optimized properly, microgrids could play a pivotal role in supporting efforts to transition to renewable energy systems and meet climate targets, finds the report published by Netherlands-based energy systems company Metabolic. The report was funded by the Dutch Ministry of Economic Affairs and the Netherlands Enterprise Agency.

Reaching that goal will require an extraordinary level of effort by any standard. But the use of microgrids--decentralised energy grids that intelligently balance the local supply and demand of distributed clean energy resources--could avoid the need for massive spending on infrastructure upgrades.
