

How many inverters can connect to Fronius datamanager

How many inverters can connect to Fronius datamanager

Installing a Fronius SnapINverter is remarkably easy. All DC and AC cabling is done in the integrated connection area of the wall bracket. The compact, lightweight inverter is simply hung into the wall bracket and snapped in. The entire installation process requires no special tools. Please note the maximum torque values marked on the side underneath the terminals.

To support you in comprehensively planning and designing PV systems when consulting and providing solutions for your customers, we offer the Fronius Solar.creator as a free, flexible and user-friendly online configuration tool.

The more shade there is, the higher the consumption of the optimiser, and the lower the efficiency. This means, especially in partial shading situations, that power optimisers often cannot compensate for the shade, so they do not generate a higher yield.

The "Fronius Arc Guard" safety function is used to detect and interrupt DC arcs in PV systems. The function was developed to comply with the IEC 63027 standard. It addresses the technical requirements for "Arc Fault Protection Equipment" (AFPE) and "Arc Fault Circuit Interruption" (AFCI) in photovoltaic systems.

The function requires specific hardware and is therefore not included in all Fronius SnapINverters. Only Symo Advanced devices have the hardware integrated and offer the "Arc Guard" function to further increase the safety of PV systems.

Fronius SnapINverters have the Fronius Datamanager 2.0 integrated ex works, but are also available in a "light" version without Datamanager. The Datamanager can also be installed into a "Light"-Device retroactively.

You can connect up to 100 SnapINverters in one system into a Solar Net communication loop using a single Datamanager 2.0 to save time and costs. However we recommend smaller loops of up to 10 devices each, to reduce the risk of differences in the electric potential and to simplify troubleshooting. The exception is the Symo Hybrid, which has a Hybridmanager integrated instead and does not support inverter-to-inverter communication via Solar Net. The Data- or Hybridmanager connects the inverter to the Internet for system monitoring on FroniusSolar.web.

With a SnapINverter with Datamanager 2.0, dynamic power reduction can be activated to limit the power fed into the grid by the system while maximizing direct self-consumption. This can also be used for zero-feed-in systems. To use this function, a Fronius Smart Meter is required for this purpose.

Dynamic power reduction of 99%-0% can also be implemented with a SnapINverter Light without

How many inverters can connect to fronius datamanager

Datamanager 2.0. For this the multifunctional power interface of the SnapINverter Light is connected to the S0 counter. In this How-To Video the technical implementation of the function is explained. In the application guide in the download box you will find additional step-by-step instructions.

Fronius SnapINverters can not only be installed in a quick and easy way, but can also be serviced efficiently. In the event of service, individual components, such as circuit boards, or the entire device can be replaced.

To keep the handling of the service case as efficient as possible, the convenient Fronius Solar.SOS service tool supports you. Using the app or browser version, you can initiate the service process online directly at the system location. All you need is a serial number or a state code. This gives you the opportunity to easily solve technical problems as well as place orders for spare parts yourself at any time, without having to call the support hotline.

With the Fronius Energy Profiling, it is possible to measure consumers and generators using more than one meter: additional secondary Fronius Smart Meters can be connected alongside the primary Fronius Smart Meter. This way the measured consumers and generators can be displayed on Fronius Solar.web. The number of additional meters that can be connected depends on how many devices are already connected to the Modbus interface. You can find a detailed explanation in the manuals linked to the right.
