

## Ultra rapid ev charging

Imagine needing a quick energy boost for your car - that's exactly what fast charging does for your electric vehicle. These EV chargers are all about getting you back on the road swiftly, with impressive charging speeds that make a big difference. They use direct current (DC) to send electricity straight into an EV's battery, skipping the slower onboard AC charger most cars use.

You'll find different speeds of chargers around, but rapid and ultra-rapid chargers work hard to cut down your waiting time. Some can pump in enough juice in about 15 minutes to give your car a good range boost - really handy when you're in a rush or on a long trip! Fast chargers, typically operating at 7kW to 22kW, are crucial for making electric cars more practical for everyone, while rapid chargers operate at 50kW and above.

The installation of these chargers is becoming more common, making it easier for you to find a charging spot, whether you're at the shopping center or on the motorway. It's all about convenience and keeping you moving.

You will find several connector types globally for DC fast charging. The Combined Charging System (CCS) is popular in Europe and North America. It combines AC and DC inlet ports into one connector, making it versatile.

In Japan, CHAdeMO connectors are common for DC charging. GB/T connectors are used mostly in China. Tesla has its own Superchargers with special plugs for their cars. These varying standards mean not all EVs can use every charger type out there--knowing which plug fits your car is crucial. However, adapters are available for some vehicles to use different charging standards, such as Tesla's CHAdeMO adapter.

Every electric car comes with a cable that matches the vehicle's onboard charger, often an AC unit for home use. For public charging stations offering faster speeds, you might need a different connector type or an adapter if available. It's important to check what your car needs before hitting the road so you won't face any surprises at charge points. The list below explains the differences between some of the chargers available.

Rapid chargers offer a quick way to boost your electric vehicle's battery on the go. They use DC fast charging technology, which allows much higher speeds than AC charging units. This means you can charge your EV to 80% capacity in as little as 15 minutes or up to an hour for most models, with the final 20% taking longer to protect battery health.

You'll find rapid chargers at service stations and public car parks across the UK. They come with different connector types like CHAdeMO and CCS, suitable for a wide range of electric cars. Rapid charging is perfect when you're traveling long distances and need to charge quickly. Power outputs vary from 50 kW to over 350 kW depending on location and charger type, making it possible to fit a substantial amount of charge during

# Ultra rapid ev charging

short stops.

This lets you charge up much quicker than with other types of chargers. A typical electric car can go from low to 80% capacity in just 15 to 60 minutes, with longer times needed to reach full capacity.

These chargers are perfect for long trips where travel time is important. Stopping for a quick coffee while your EV gets enough power for the next few hundred miles is common across service stations in the U.K. Ultra-rapid chargers make this possible and are often found along motorways and in public charging networks.

Fast chargers offer a middle ground in EV charging. They provide quicker charging than slow chargers but don't match the speed of rapid or ultra-rapid stations. Typically, these units supply AC power at 7 kW to 22 kW, which is converted to DC within your vehicle by the onboard charger, allowing for faster replenishment of the battery.

They deliver power ranging from 7 kW to 22 kW, which allows drivers to charge their cars within a couple of hours--much faster than with a standard home charger but slower than their rapid counterparts.
