

Utility-scale energy storage chad

Utility-scale energy storage chad

Chad's first solar hybrid plant operates in two modes, injecting power into the main or a designated grid section based on genset status. ePowerControl PPC ensures efficient BESS synchronization and mode management for sustainability.

The plant's estimated annual energy production of 14,482,300 kWh will cover Ab'ch's electricity needs, benefiting the city's 80,000 residents. The project saves an impressive 5 million liters of diesel annually.

Despite pandemic challenges, the EPC team efficiently commissioned the plant's controller remotely. Coupled initially with existing generators, the project exemplifies a greener, cost-effective approach for Ab'ch.

Plus and minus signs indicate the poles on the new energy storage facility at the Fraunhofer Institute in Magdeburg, Germany. During a full-scale test, the entire Fraunhofer research center was supplied with energy from the battery. The lithium-based storage system has an available capacity of 0.5 megawatts per hour and an output of one megawatt. The storage battery is housed in a 26-ton transportable container. This type of equipment is designed to stabilize intermittent and variable energy.

The Utility-Scale Energy Storage solution is an enabling solution that facilitates the adoption of other Project Drawdown solutions, such as Distributed Solar Photovoltaics. As a result, we don't model emissions reductions and financial impacts associated with utility-scale energy storage here, but account for them in those solutions.

Utilities have long operated on the model of producing sufficient electricity to meet demand in real time. To supplement large coal, gas, or nuclear plants, they rev up highly polluting "peaker" plants as needed.

Energy storage makes it possible to use power generated at a time other than when it is consumed. A power system with large-scale energy storage can use various types of generation in an optimal fashion. Large centralized generators can run at a steady rate, with no need to undergo inefficient cycling to respond to changes in demand. If the power generated by solar or wind installations exceeds demand, it can be stored rather than wasted.

Storage can also relieve congestion on transmission lines, increase reliability and performance, and allow for the efficient use of existing infrastructure. Moreover, storage makes the power system more resilient, reducing outages and aiding in emergency preparedness.

Energy can be stored in many forms, including: (1) gravitational potential energy (pumped hydroelectric

energy storage); (2) chemical energy (batteries); (3) mechanical energy (flywheels or compressed air energy storage); (4) thermal energy storage (molten salt); and (5) hydrogen storage.

Project Drawdown's Utility-Scale Energy Storage solution involves the use of new technologies and practices to store energy on a utility level. This solution does not replace a conventional practice, but is key to developing variable renewable energy sources.

According to the USDepartment of Energy's global energy storage databases (2019), there are 1,687 large-scale energy storage operational systems worldwide with a total capacity of 191 gigawatts. Some 95 percent of this capacity is composed of pumped hydroelectric technology, with more than 350 large projects installed worldwide. Other storage technologies include thermal (1.7 percent) and electromechanical (1.4 percent) storage. In 2017, lithium-ion batteries accounted for nearly 90 percent of large-scale battery storage additions (IEA, 2018).

The primary use of energy storage at present is power arbitrage (time shift): pumped hydropower facilities buy electricity at night when prices are low and use it to pump water from a low reservoir to an elevated one. During the day, when prices are high, the stored water is allowed to run downhill through turbines, generating electricity that can then be sold back to the grid. The remaining energy storage is used to enable penetration of variable renewable generation sources.
